Case	Description	Outcome	Comments
1	A 45-year-old male with a history of chronic alcoholism and liver disease presented with a 2-week history of progressive weakness and fatigue. He had no fever, chills, or weight loss. Physical examination was unremarkable. Laboratory studies showed a hemoglobin of 10 g/dL, hematocrit of 30%, and a reticulocyte count of 1.5%. A peripheral blood smear showed microcytic, hypochromic red blood cells with a few schistocytes. A bone marrow examination showed a hypercellular marrow with a normal myeloid-to-erythroid ratio. A liver biopsy showed mild chronic hepatitis. A trial of oral iron therapy was initiated.	The patient's symptoms improved over the next 4 weeks, and his hemoglobin increased to 12 g/dL. The reticulocyte count decreased to 0.5%.	The patient's symptoms were likely due to iron deficiency anemia secondary to chronic alcoholism and liver disease. The liver biopsy showed mild chronic hepatitis, which is a common finding in patients with alcoholism.
2	A 60-year-old female with a history of rheumatoid arthritis and long-term use of low-dose prednisone presented with a 3-month history of progressive weakness and fatigue. She had no fever, chills, or weight loss. Physical examination was unremarkable. Laboratory studies showed a hemoglobin of 9 g/dL, hematocrit of 27%, and a reticulocyte count of 0.8%. A peripheral blood smear showed microcytic, hypochromic red blood cells with a few schistocytes. A bone marrow examination showed a hypercellular marrow with a normal myeloid-to-erythroid ratio. A trial of oral iron therapy was initiated.	The patient's symptoms improved over the next 4 weeks, and her hemoglobin increased to 11 g/dL. The reticulocyte count decreased to 0.3%.	The patient's symptoms were likely due to iron deficiency anemia secondary to long-term use of low-dose prednisone. The bone marrow examination showed a hypercellular marrow with a normal myeloid-to-erythroid ratio, which is consistent with iron deficiency anemia.
3	A 35-year-old male with a history of chronic kidney disease and long-term use of low-dose prednisone presented with a 2-month history of progressive weakness and fatigue. He had no fever, chills, or weight loss. Physical examination was unremarkable. Laboratory studies showed a hemoglobin of 8 g/dL, hematocrit of 24%, and a reticulocyte count of 0.5%. A peripheral blood smear showed microcytic, hypochromic red blood cells with a few schistocytes. A bone marrow examination showed a hypercellular marrow with a normal myeloid-to-erythroid ratio. A trial of oral iron therapy was initiated.	The patient's symptoms improved over the next 4 weeks, and his hemoglobin increased to 10 g/dL. The reticulocyte count decreased to 0.2%.	The patient's symptoms were likely due to iron deficiency anemia secondary to long-term use of low-dose prednisone. The bone marrow examination showed a hypercellular marrow with a normal myeloid-to-erythroid ratio, which is consistent with iron deficiency anemia.
